

2.3.4.6 Geographic Jurisdiction Data Governance

[Return to Data Taxonomy](#)

Overview

[Return to Top](#)

Geographic Jurisdiction Data Governance is the judicial (legal and contractual/policy) considerations that are applicable within and across physical geographic boundaries/areas. ¹⁾

Originally, before the ubiquitous use of networks and internet, hardware abstraction, virtualization, the explosion in cloud computing, and globalization of tech companies, data protection was relatively easy which a large portion of the Data Protection accomplished through [Physical Security](#). These original concepts of Data Protection were greatly expanded to cover [Securability](#). Although, this was an improvement in protecting data from the perspective of the corporation, there was little protection for the end-user (i.e., consumer) from the corporations. Figure 1 represents the widespread nature of Geographic Jurisdiction Data Governance. Fortunately, most of the tech areas such as Cloud Computing, Artificial Intelligence and Big Data have already made adaptations for Geographic Jurisdiction Data Governance especially since it has been mandated by [International and national Governance and Regulation](#) such as [General Data Protection Regulation \(GDPR\)](#), [Data Protection Act 2018](#), and [California Consumer Privacy Act \(CCPA\)](#).

Figure 1: Geographic Jurisdiction Data Governance touches most technical areas see ²⁾

Unfortunately, most distributed computing platforms (i.e., DIDOs) have done little to address Geographic Jurisdiction Data Governance even while the amount of governance and regulation has increased become relatively mainstream internationally. Some of the Countries that have enacted data protection laws are <https://incountry.com/country-compliance/>, <https://incountry.com/blog/data-residency-laws-by-country-overview/>:

- China
- Russia
- India
- Indonesia
- Saudi Arabia
- Switzerland
- Turkey
- United Arab Emirates
- United States of America
- State of California

Kinds of Geographic Jurisdiction

[Return to Top](#)

There are three main categories of Geographic Jurisdiction Data Governance: [data_residency](#), [Data Sovereignty](#) and [Data Localization](#). Usually, these concepts are applied strictly to data storage with an increase burden to store the data in the jurisdiction where the data is created. Basically, it represents the [Data-at-Rest](#) data state, see: [2.3.4.2 State of Data Taxonomy](#).

Data Residency

[Return to Top](#)

Data Residency refers to where a business, industry body or government specifies that their data is stored in a geographical location of their choice, usually for regulatory or policy reasons.

A typical example of a Data Residency requirement in action is where a company wishes to take advantage of a better tax regime. Doing so will usually require the business to prove they are not conducting too great a proportion of core business activities outside that country's borders – including the processing of data. They will therefore impose a Data Residency that requires them to use certain infrastructures, and then impose strict data management workflows on themselves and any cloud service providers in order to protect their taxation rights.³⁾

Data Sovereignty

[Return to Top](#)

Data Sovereignty differs from Data Residency in that not only is the data stored in a designated location, but is also subject to the laws of the country in which it is physically stored. This difference is crucial, as data subjects (any person whose personal data is being collected, held or processed) will have different privacy and security protections according to where the data centers housing their data physically sit.

This difference is also crucial for businesses, as a government's rights of access to data found within its borders differ widely from country to country. This is where data sovereignty and residency are often conflated. Ensuring data sits within a geographical location for whatever reason - whether avoiding or taking advantage of laws, regulations and tax regimes, or even for pure preference and comfort - is a matter of Data Residency. But the principle that the data is subject to the legal protections and punishments of that country is a matter of data sovereignty.

They are clearly related, and even two sides of the same coin, but one is a matter of national legal rights and obligations, while the other is a matter of geography. Recognizing this distinction will help professionals better prepare for compliant data management and exchange.⁴⁾

Data Localization

[Return to Top](#)

Data Localization is the most stringent and restrictive concept of the three, and like data sovereignty, is a version of Data Residency predicated on legal obligations. It is also the concept that is growing the fastest internationally.

Data Localization requires that data created within certain borders stay within them. In contrast to the two terms above, it is almost always applied to the creation and storage of personal data, with exceptions including some countries' regulations over tax, accounting and gambling.

In many cases, Data Localization laws simply require that a copy of such data be held within the country's borders, usually to guarantee that the relevant government can audit data on its own citizens (provided there is due cause) without having to contend with another government's privacy laws. India's draft Personal Data Protection Bill is an example of exactly this (you can see more discussion of the Bill in our Director of Data Privacy Services' blog here).

However, there are countries where the law is so strict as to prevent it crossing the border at all. For instance, Russia's On Personal Data Law (OPD-Law) requires the storage, update and retrieval of data on its citizens to be limited to data center resources within the Russian Federation.⁵⁾

===== Geographic Jurisdiction Concerns ===== [Return to Top](#) The main emphasis of Julian Box's

article is on Cloud Computing, many of the concerns and issues he raises are pertinent to Distributed Computing since the data within the distributed solution potentially can reside anywhere, especially with a [Permissionless Network](#). As a starting point, try applying the above distinctions to these key questions about your own infrastructure: * Where are each of your various categories of data (personal data, financial records, etc) created or processed and what obligations might this bring? * Where is it then stored, and who owns the data center? Your data may be in a data center in the UK, but if this data center is owned by a US-headquartered company, then the US Government may have the rights to access your data under the CLOUD Act. * What are your procedures for back-up? Where is your data backed up to? According to the type of data in question, what local stipulations exist for the security or encryption of that data? * How confident are you in your cloud partner(s) understanding of current and future data privacy regulations? How have they evidenced that their data centers meet all your local and global privacy needs, or have you assumed it? ~~~DISCUSSION:on|Outstanding Issues~~ ~~~DISCUSSION:off~~
