

2.3 Taxonomic Views

[return to Architectural Views](#)

A [taxonomy](#) is a way of organizing things into useful and convenient classes. Each class can then be treated as an abstraction of the individual elements. For example, **Dog** is a class of **Animal**. Once an individual entity is classified as a **Dog**, generalizations can be made about what to expect from the individual entity.

There can be many Taxonomies that classifies entities. For example, there is a classification which places and individual in to the animal kingdom, there can also be a taxonomy that classifies an individual according to the employment (working, retired, etc).

There are four different taxonomies that are useful within a DIDO.
