

# Public Key

[Return to Glossary](#)

## Definition 1

A **Public Key**<sup>1)</sup> is a cryptographic key used with a **Public Key Cryptographic Algorithm** that is uniquely associated with an entity and that may be made public. In an asymmetric-key (**Public Key**) cryptosystem, the **Public Key** has a corresponding **Private Key**. The **Public Key** may be known by anyone and, depending on the algorithm, may be used, for example:

1. Verify a digital signature that was generated using the corresponding **Private Key**,
2. Encrypt keys that can be decrypted using the corresponding **Private Key**, or
3. Compute a shared secret during a key-agreement transaction.

## Definition 2

In **cryptology**, a **Public Key** is a large numerical value that is used to encrypt data. The **key** can be generated by a software program, but more often, it is provided by a trusted, designated authority and made available to everyone through a publicly accessible repository or directory.

A **Public Key** is also used to encrypt a message or check the legitimacy of a **digital signature**. It is accompanied by a corresponding **private key**, which is known only to its owner. Private keys are used to decrypt messages that were created with the corresponding **Public Key** or to create signatures. In other words, a **Public Key** locks up data from unauthorized use, while a private key is used to unlock it.

**Public Keys** are available from a certificate authority, which issues digital certificates that prove the owner's identity and contain the owner's **Public Key**. **Public Keys** are created using an asymmetric algorithm, which pairs the **Public Key** with an associated private key. The most common algorithms used to generate **Public Key** are Rivest-Shamir-Adleman, elliptic curve cryptography, and Digital Signature Algorithm.

A **Public Key** can be given to any person with whom an individual wants to communicate, whereas a private key belongs to the individual it was created for and isn't shared. The **Public Key** is typically stored on a **Public Key Infrastructure (PKI) server** and is used to encrypt data securely before it is sent over the **internet**.
