

# TRESOR

[Return to Glossary](#)

**TRESOR** is a software approach that seeks to resolve this insecurity by storing and manipulating encryption keys almost exclusively on the [Central Processing Unit \(CPU\)](#) alone, and in [Registers](#) accessible at [Protection Rings Ring 0](#) (the highest privilege level) only—the exception being the brief period of initial calculation at the start of a session. This ensures that encryption keys are almost never available via user space or following a cold boot attack. **TRESOR** is written as a kernel patch that stores encryption keys in the x86 debug registers, and uses on-the-fly round key generation, atomicity, and blocking of usual **ptrace** access to the debug registers for security.
